**PRUEBAS MECÁNICAS EN LOS MATERIALES.**

<b>ÍNDICE</b>	<b>PÁGINA</b>
1.- Clasificación de los materiales.	2
2.- Estructura de los materiales:	6
⇒ Metales	
⇒ Polímeros	
3.- Propiedades y características mecánicas básicas.	13
4.- Máquinas, accesorios, aditamentos e instrumentos de medición.	25
Bibliografía	

## 1.- Clasificación de los Materiales

### 1.- Ferrosos:

Aceros :        Ordinarios  
                 Aleados

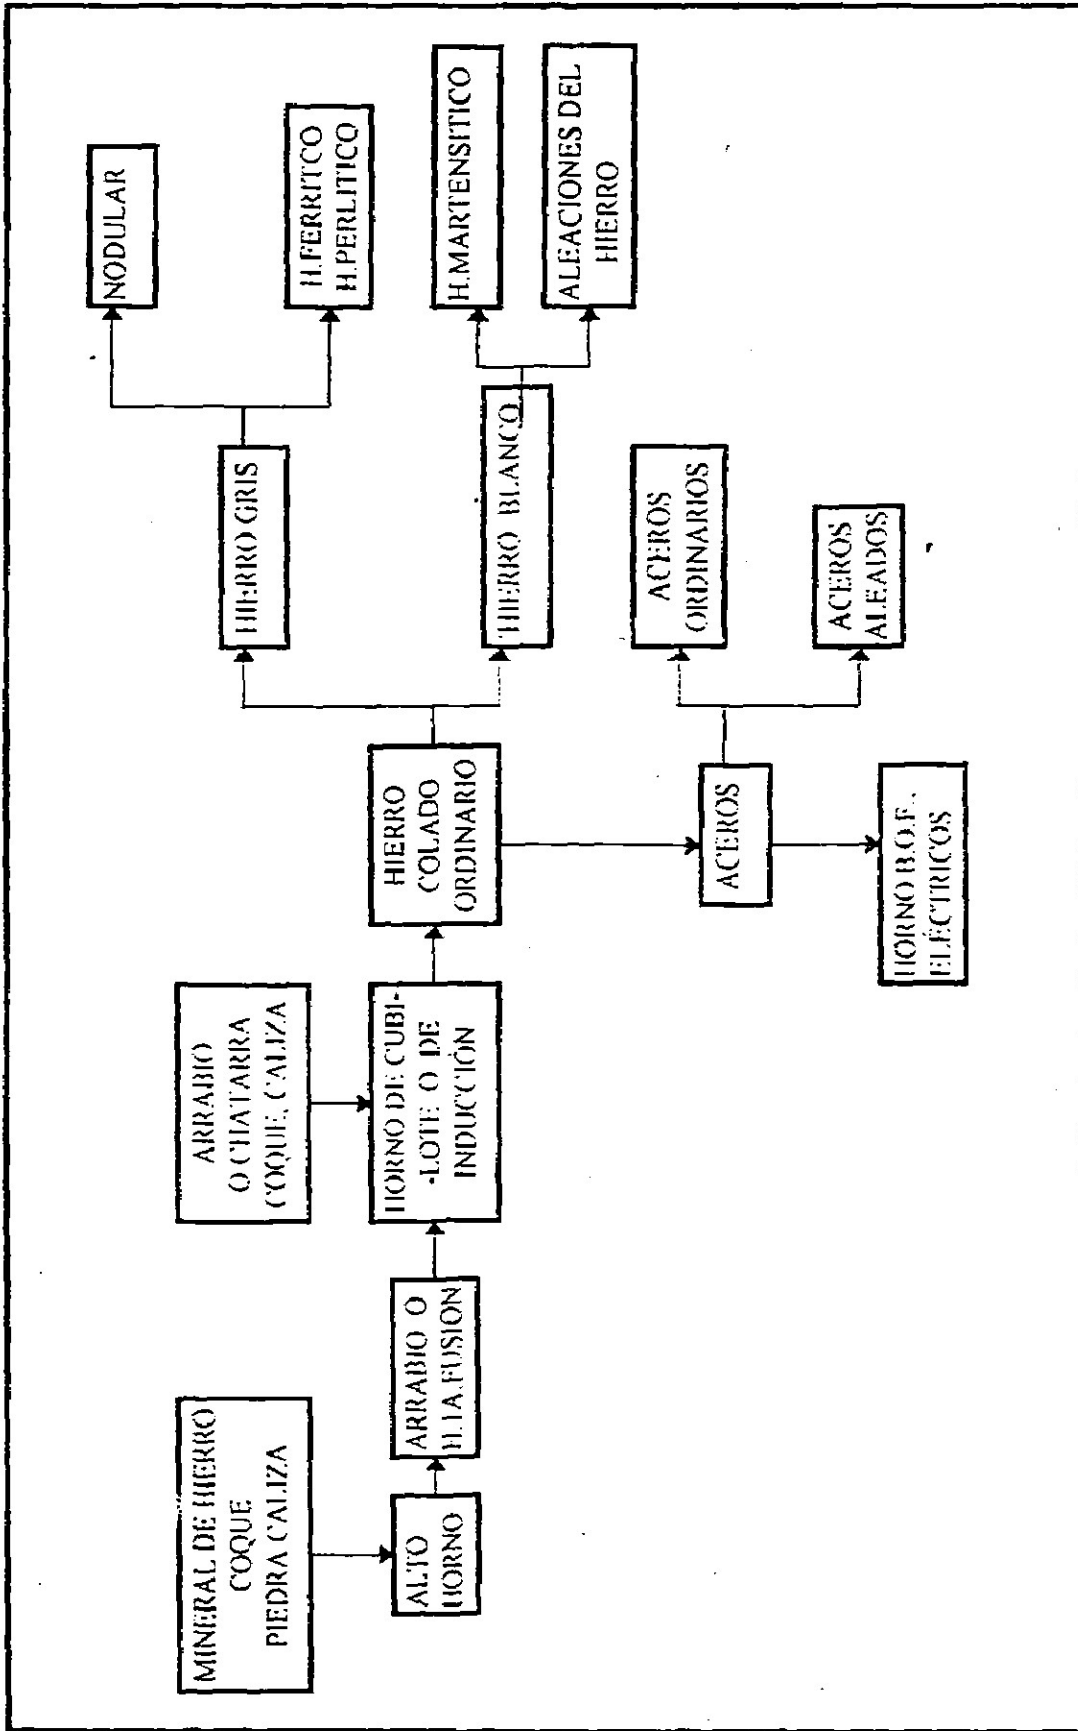

Fundiciones: Grises: Nodular  
   Ferrítico  
   Perlítico  
                 Blancas:        H. Martensíticos  
   Especiales Aleaciones

2.- No-Ferrosos:    Cobre y sus Aleaciones  
                         Aluminio y sus Aleaciones  
                         Níquel, Cromo, Estaño, etc.

3.- Orgánicos:     Madera  
                         Polímeros  
                         Elastómeros

4.- Inorgánicos:    Fibras Compuestas  
                         Cerámicos  
                         Vidrios  
                         Minerales

# DIAGRAMA DE OBTENCIÓN DEL HIERRO Y EL ACERO

## MECANISMOS DE CRISTALIZACIÓN EN LOS METALES

ES EL PROCESO DE TRANSFORMACIÓN DE UN ESTADO LÍQUIDO A UNO SÓLIDO DESARROLLÁNDOSE LOS CRISTALES EN FORMA ORDENADA.

TEMP. ALTA

FORMACIÓN DE  
NÚCLEOS DE  
ÁTOMOS

FORMACIÓN DE  
DENDRITAS

CRECIMIENTO DE  
CRISTALES

TEMP. NORMAL

FORMACIÓN DE  
LÍMITES DE  
GRANO

## 2.- Estructura de los Materiales

### METALES

**PARA METALES:** su estructura está compuesta por agrupamiento de átomos.

**Estados de la Materia en la Obtención de un Metal**

- \* Gaseosos
- \* Líquidos
- \* Sólidos

**Tipos de Enlaces**

- \* Iónico
- \* Metálico
- \* Covalente
- \* Vander-Walls
- \* Puente de Hidrógeno

**Red o estructura cristalina:** agrupación de átomos en forma ordenada denominadas celdillas espaciales.

**Características de la red:**

- \* Sus longitudes
- \* Sus ángulos

## LOS SIETE SISTEMAS CRISTALINOS

### 1.- Monoclínico

- a) Simple
- b) De extremos centrados

### 2.- Triclínico

- a) Simple

### 3.- Hexagonal

- a) Con extremos centrados

### 4.- Romboédrico

- a) Simple

### 5.- Ortorrómico

- a) Simple
- b) Cuerpo centrado
- c) Extremos centrados
- d) Caras centradas

### 6.- Tetragonal

- a) Simple
- b) Cuerpo centrado

### 7.- Cúbico

- a) Simple
- b) Cuerpos centrados
- c) Caras centradas

**Los sistemas de cristalización más comunes son:**

- ⇒ Cúbico\*
- ⇒ Hexagonal\*
- ⇒ Tetragonal
- ⇒ Ortorrómbico
- ⇒ Romboédrico

**Defectos o imperfecciones del cristal:**

- ⇒ Vacancias
- ⇒ Intersticios
- ⇒ Dislocaciones (Borde y Helicoidales)

**Polimorfismo o Alotropía:** es cuando el material se presenta en varias formas

\* En metales

**REDES ESPACIALES O TIPOS DE ESTRUCTURAS CRISTALINAS**

Los siete sistemas de estructura cristalina y las 14 redes de Bravais.

## ESTRUCTURA DE LOS POLÍMEROS

Son macromoléculas orgánicas que a través de un enlace químico forman el monómero ( o unidad monomérica), el cual se repetirá millones de veces en cadenas lineales o cruzadas para finalmente constituir un polímero.

Ejemplo:

Unidades repetitivas y grupo funcional para algunos de los polímeros que tienen estructura de cadena cruzada:

Polímero	Estructura	Repetición a la unidad (%)	Monómero (%)	Grupos funcionales (%)	Unidad (%)
Polietileno (acetato)		9,500-12,000	75-78	300	1.42
Polietileno (dicloro)		8,000-12,000	50-55%	400-500	1.00
Policloropreno		9,000-11,000	110-120	200-400	1.2
Celulosa		2,000-2,000	5-50	200-250	1.20

## POLÍMEROS

### **CARACTERÍSTICAS GENERALES DE LOS POLÍMEROS:**

- \* Ligeros
- \* Resistentes a la Corrosión
- \* Aislantes Eléctricos
- \* Baja Resistencia a la Tensión
- \* No usados en Temperaturas Altas
- \* Muy usual

### **CLASIFICACIÓN DE LOS POLÍMEROS:**

#### **Según su Mecanismo de Polimerización:**

**Polímeros por adición:** son cadenas formadas por el enlace covalente de las moléculas.

**Polímeros por condensación:** se producen cuando se unen dos o más tipos de moléculas mediante una reacción química que libera agua.

#### **Según su Estructura:**

**Polímeros lineales:** son cadenas largas de moléculas, que son formadas por una reacción de adición o condensación.

**Polímeros de red:** son estructuras reticulares tridimensional producidos mediante un proceso de enlaces cruzados que implica una reacción de adición condensación.

#### **Según su Comportamiento:**

**Polímeros termoplásticos:** son polímeros de estructura lineal, que se comportan de manera plástica a elevadas temperaturas y pueden ser conformados a temperaturas elevadas, enfriados y luego recalentados y conformados.

**Polímeros termoestables o termofijos:** son de red o estructura tridimensional **reticulado** por lo que se consideran rígidos y no se ablandan cuando se calientan se forman por reacción de condensación no se pueden reprocesar debido a que parte de las moléculas salen del material.

**Según su Grado de Polimerización:**

- \* Homopolímeros (un sólo material)
- \* Copolímeros (dos o más tipos)
- \* Oligopolímeros (pocos monómeros)
- \* Polímeros

**Según su Naturaleza:**

- \* Naturales (lino, seda, asbesto, celulosa)
- \* Artificiales o sintéticos (rayón, nitrato de celulosa)
- \* Según su origen
- \* Vegetales (algodón, celulosa, etc.)
- \* Animales (pelos)
- \* Minerales (asbestos, fibra de vidrio)

## POLÍMEROS INORGÁNICOS:

Son macromoléculas que se constituyen de cadenas que no contienen átomos de carbono.

### Clasificación:

**Naturales:** Asbestos  
Fibras de carbono o de grafito obtenidas por extrusión.

**Artificiales:** Fibra de vidrio  
Silicones

## ELASTOMEROS

**Elastómero (caucho o hules):** es una cadena polimérica que se encuentra enrollada debido al arreglo cis de los enlaces, por lo que al aplicarse una fuerza se alarga al desenrollarse las cadenas lineales, deslizándose unas sobre otras y provocando una combinación de deformación plástica y elástica. Tienen un comportamiento intermedio y la capacidad de deformarse elásticamente en alto grado sin cambiar de forma.

### 3.- Propiedades y Características Mecánicas en los Materiales

**OBJETIVO DE LA PRÁCTICA:** es el de conocer la manera de obtener las características y propiedades mecánicas básicas.

**TEORÍA:** basandonos en un ensayo estático de tensión y su gráfica de comportamiento esfuerzo vs deformación unitaria, obtendremos la siguientes características y propiedades mecánicas básicas en los materiales.

- \* Resistencia Mecánica
- \* Ductilidad
- \* Rígidez
- \* Resilencia
- \* Tenacidad
- \* Estándares de Probetas
- \* Velocidad del Ensayo
- \* Textura de Grano y Tipos de Fallas

**Resilencia Mecánica:** es la oposición que ofrece el material a través de su fuerza interna (molecular) a la fuerza o carga aplicada.

**Esta se mide a través de:**

**1.- Límite Proporcional ( $\sigma_{LP}$ ):** es el mayor esfuerzo que un material es capaz de desarrollar sin perder la proporcionalidad entre esfuerzo y deformación, es decir, que representará el último punto en la pendiente de la gráfica, cumpliendo con la ley de hooke.

**2.- Límite Elástico ( $\sigma_{LE}$ ):** es el mayor esfuerzo que un material es capaz de desarrollar sin que ocurra la deformación permanente al retirar el esfuerzo, la determinación de este límite elástico no es práctico y rara vez se realiza.

**3.- Resistencia a la Cedencia ( $\sigma_{Y.P.}$ ):** es el esfuerzo al cual ocurre un aumento de deformación para cero incremento de esfuerzo.

En este punto cede el material a los defectos de cristal (vacancias, intersticios y dislocaciones) por lo que provoca el desplazamiento molecular (deformación) sin oponerse a la fuerza aplicada por lo que los incrementos de carga en la máquina de pruebas para algunos materiales.

**4.- Resistencia Máxima ( $\sigma_{max.}$ ):** es el esfuerzo máximo que puede desarrollar el material debido a la carga aplicada, durante un ensaye hasta la roptura. (Se observa en la probeta el inicio de la reducción de área en materiales dúctiles).

**5.- Esfuerzo de Roptura ( $\sigma_{RUP.}$ ):** es el esfuerzo nominal al ocurrir falla y se obtiene dividiendo la carga decreciente registrada en la carátula o pantalla de la máquina y el área inicial de la probeta.

**6.- Esfuerzo de Roptura Real o Verdadero ( $\sigma_{RUP.}$ ):** es el esfuerzo nominal al ocurrir la falla y se obtiene dividiendo la carga entre el área real que disminuye conforme se aplica ésta.

Este esfuerzo es improbable sobre la sección crítica o de falla, ya que el laminado del metal causa el desarrollo de una compleja distribución de esfuerzos.

## OBTENCIÓN DEL PUNTO DE CEDENCIA:

Se define como el esfuerzo al cual ocurre una gran deformación sin incremento de carga o esfuerzo.

En algunos materiales este punto de cedencia no se presenta como en otros, que a través de la oscilación de la aguja en la carátula de la lectura de carga o del canal en el display de carga, se puede detectar dicho punto en máquina universal.

El método para determinar el punto de cedencia se le conoce como método "offset" o "desplazamiento".

El método consiste en trazar una línea o recta paralela a la pendiente de la gráfica a partir de un valor de deformación unitaria de 0.001, 0.002, 0.003 in/in. Que representará 0.1%, 0.2%, 0.3% de deformación unitaria. El valor más usual es el 0.2% ver figura 3.2.

Figura 3.2

## ZONAS EN LA GRÁFICA:

1.- **Zona Elástica:** se considera desde el origen hasta el punto límite proporcional. Se emplea en el diseño de elementos de máquinas y estructuras.

2.- **Zona Plástica:** se considera desde el punto de cedencia hasta el punto de esfuerzo máximo.

Se emplea para darle forma al material por ejemplo los procesos de mecanizado (torneado, troquelado, doblado, extruido, etc.), laminados (en caliente y en frío). Esta zona se divide: en zona de cedencia y zona de endurecimiento por deformación.

3.- **Zona Hiperplástica:** se considera en algunos materiales desde el punto de de esfuerzo máximo hasta el punto de roptura aparente.

Se emplea en el diseño de elementos de máquinas, productos y estructuras que deben absorber grandes cantidades de energía meánica (energía cinética o potencial).

Figura 3.3

## **DUCTILIDAD**

Es la propiedad que tienen los materiales de deformarse en grande.

## **FRAGILIDAD**

Es la propiedad que tienen los materiales de no presentar deformación macroscópica.

### **Estas propiedades son medidas:**

\* **Para el Ensayo de Tensión a través de:**

-**% de Elongación:** se obtiene midiendo la longitud inicial ( $L_o$ ) y la final ( $L_f$ ) de la probeta y luego sustituyendo en la ecuación:

$$\% \text{ Elong.} = (L_f - L_o) / L_o \times 100$$

-**% de Reducción de Área:** se obtiene midiendo el diámetro inicial y final de la probeta, calculando el área respectiva y sustituyendo en la ecuación:

$$\% \text{ de Reducción de Área} = (A_o - A_f) / A_o \times 100$$

\* **Para el Ensayo de Compresión a través de:**

-**% de Aumento de Área:** se obtiene midiendo los diámetros inicial y final, calculando el área respectiva y sustituyendo en la ecuación:

$$\% \text{ de Aumento de Área} = (A_f - A_o) / A_o \times 100$$

- **% de Reducción de Longitud:** se obtiene midiendo la longitud inicial y final de la probeta y sustituyendo en la ecuación:

$$\% \text{ de Reducción de Longitud} = (L_o - L_f) / L_o \times 100$$

**Se recomienda que los materiales que tengan un % de elongación, % de reducción de área, % de aumento de área, % de reducción de longitud, mayor de 5 %, para que se consideren dúctiles.**

Figura 3.4

**RIGIDEZ:**

Es el esfuerzo requerido para producir una deformación dada.

Se mide a través de la obtención del módulo de elasticidad para carga axial ( $E$ ) y representa la tangente de la pendiente en la gráfica esfuerzo vs deformación, este módulo se puede obtener considerando dos puntos sobre la pendiente y realizando un triángulo como se muestra en la figura 3.5

$$E = \text{Tg } \theta = \Delta\sigma / \Delta\varepsilon = (\sigma_2 - \sigma_1) / (\varepsilon_2 - \varepsilon_1)$$

Figura 3.5

Material	Modulo Elástico (E)			
	#	X10 <sup>6</sup> (kg / cm <sup>2</sup> )	(MPa)	(10 <sup>6</sup> X / IN)
Acero Ordinario		2.1	200	30
Aluminio		0.705	70	10
Latón		0.98	100	11
Hierro Colado		1.05	120	11.6
Madera		0.09	183	1.2
Concreto		0.25	500	3.5
Plástico		0.56	116	0.8

Valores promedio de modulo de elasticidad de algunos materiales  
Tabla 1.1

### RESILENCIA ELÁSTICA:

Es la propiedad que tienen los materiales de absorber energía hasta su límite proporcional o elástico (energía elástica).

Otras definiciones son: una medida de la resistencia a la energía elástica.

La resiliencia elástica unitaria (R.E.U.) o módulo de resiliencia: es la energía almacenada por unidad de volumen en límite elástico o proporcional; y representa el área (A1) bajo la pendiente de la gráfica  $\sigma$  vs  $e$  mostrada en la figura 3.6.

$$REU = A1 = \sigma_{LP}^2 / 2\varepsilon_{LP} \text{ (kg - cm / cm}^3\text{)}$$

$$\text{Volumen Inicial (Vo)} = A_o \times L_o \text{ (cm}^3\text{)}$$

$$\text{Resiliencia Elástica Total (RET)} = REU \times V_o.$$

$$RET = \sigma_{LP}^2 / 2\varepsilon_{LP} \times V_o \text{ (kg - cm)}$$

L.P.: Límite proporcional.

Figura 3.6

**TENACIDAD:**

Es la propiedad que tienen los materiales de absorber energía hasta el punto de rotura (energía plástica).

Representa el área total bajo la gráfica esfuerzo-deformación, esta se puede medir a través de seccionar el área en áreas regulares y sumarlas, o con el planímetro, que es un instrumento para determinar el área de una gráfica. Al seguir el contorno de la misma. El valor así obtenido será la tenacidad unitaria.

**Tenacidad Unitaria (TU) = Area total**

$$TU = (\sigma_{\max} + \sigma_{YP}) \epsilon_{\max} / 2 \text{ (kg - cm / cm}^3\text{)}$$

$$\text{Volumen Inicial (Vo)} = A_o \times L_o \text{ (cm}^3\text{)}$$

**Tenacidad Total (TT) = TU x Vo (kg - cm)**

YP (Yield Point): Punto de cedencia.

Figura 3.6a

### ESTANDAR DE PROBETAS PARA TENSIÓN:

Las probetas para ensayos de tensión se realizan de diferentes formas la sección transversal del espécimen puede ser redonda, rectangular o irregular según sea el caso.

Las formas dimensionales de la probeta depende de las asignaciones que estipule las normas referidas por las agencias de ensaye e inspección en los materiales y productos.

La porción del tramo recto es de sección menor que los extremos para provocar que la falla ocurra en una sección donde los esfuerzos no resulten afectados por los aditamentos de sujeción (ver figura 3.7).

El tramo de calibración es el marcado según estandar, sobre el cual se miden las lecturas de longitud final y diámetro final los extremos de las probetas redondas, y rectangulares, pueden ser simples, cabeceados o roscados, los extremos simples deben ser largos para adaptarse algún tipo de mordaza cuneiforme o plana (ver figura 3.8).

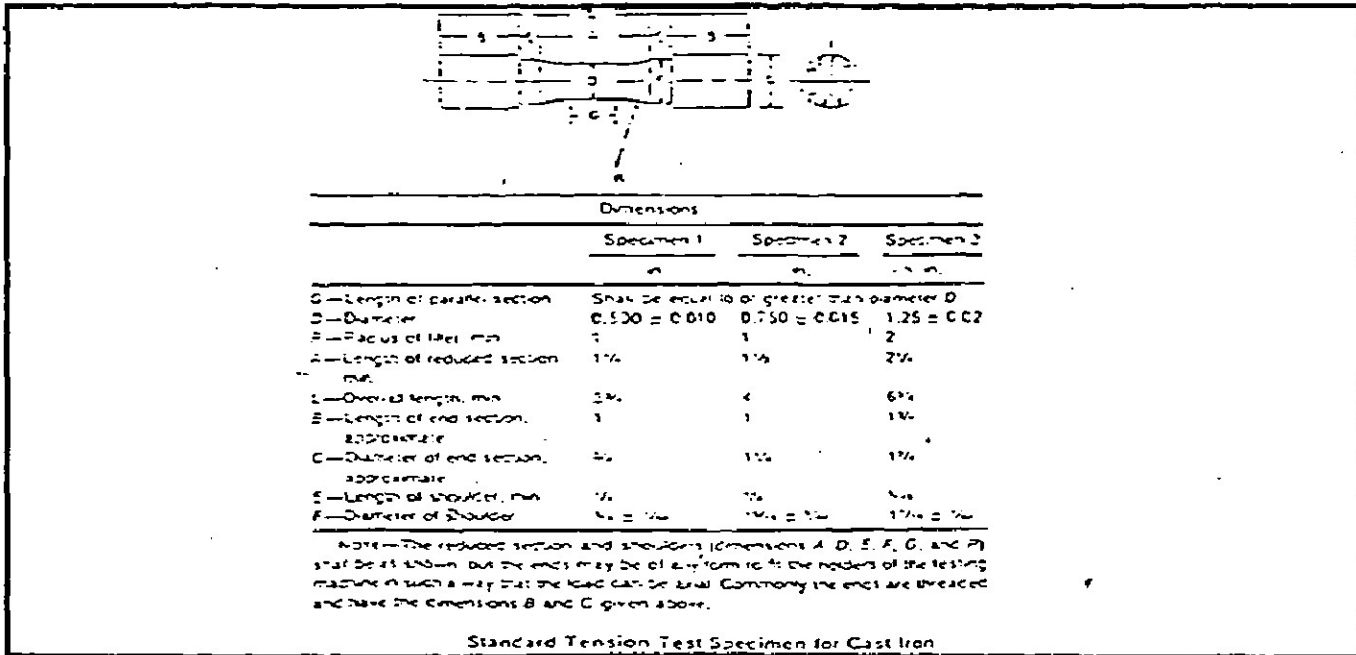

Figura 3.7

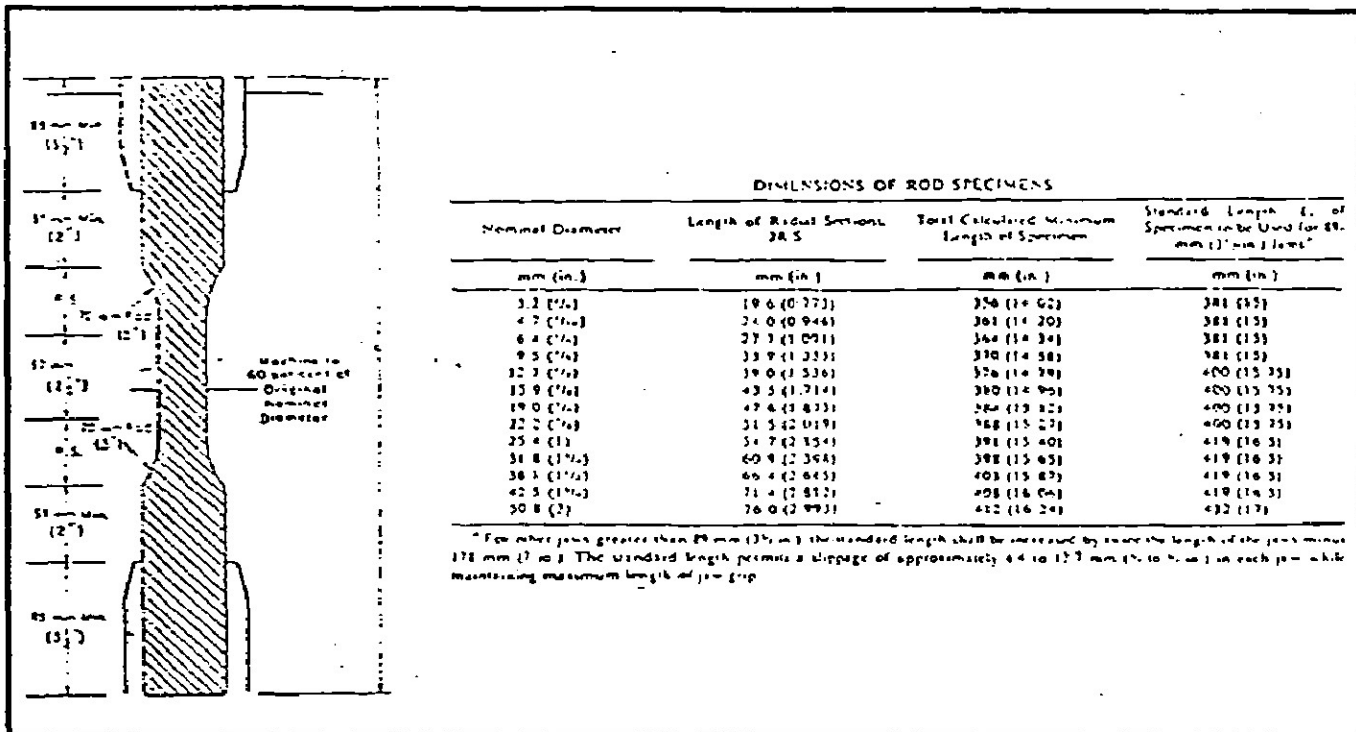

Figura 3.8

Una probeta debe ser simétrica con respecto a un eje longitudinal a lo largo de su longitud para evitar la flexión durante la aplicación de la carga (ver figura 3.8), la longitud de la sección reducida depende de la clase de material y de las mediciones que se tomen.

En las siguientes figuras 3.9 y 3.10 se muestran los diferentes estándares para los ensayos estáticos de tensión.

Figura 3.9

Specimen Dimensions for Tensile Test*						
Dimension (see drawings)	Parameter		Over Size		Tolerances	
	Type I	Type II	Type III	Type IV <sup>†</sup>		
M - Width of narrow section**	12	6	3	1	±0.05	
L - Length of narrow section	57	57	27	22	±0.05	
W - Width over all min <sup>†</sup>	18	16	8	1.5	±0	
LO - Length overall, min <sup>†</sup>	165	145	140	110	±0 max	
G - Gauge length <sup>†</sup>	50	50	25	20	±0.05	
C - Gauge length <sup>†</sup>					±0.15	
D - Distance between grips	115	120	115	100	±1	
R - Radius of fillet	75	75	35	24	±1 <sup>†</sup>	
RO - Outer radius (Type IV)				25	±1	

Specimen Dimensions for Tensile Test*						
Dimension (see drawings)	0.25 or under		Over 0.25 to 0.49 end		Tolerances	
	Type I	Type II	Type III	Type IV <sup>†</sup>		
M - Width of narrow section**	0.50	0.25	0.25	0.25	±0.02	
L - Length of narrow section	1.25	1.25	1.25	1.25	±0.02	
W - Width over all, min <sup>†</sup>	0.75	0.75	1.25	0.75	±0.25	
LO - Length overall, min <sup>†</sup>	4.5	3.5	4.5	4.5	±0 max	
G - Gauge length <sup>†</sup>	2.00	2.00	2.00	2.00	±0.016 <sup>†</sup>

R - Radius of fillet	3.00	3.00	3.00	0.50	±0.14 <sup>†</sup>	
RO - Outer radius (Type IV)				1.00	±0.24	

\*Tensile Test Specimens for Sheet, Plate, and Welded Plates

Figura 3.10

Otros estándares para polímeros o plásticos se encuentran en la asignación de la ASTM D 412, hasta D 530, hasta D 638; para concreto ASTM C 190; para materiales eléctricos ASTM D 651, etc.

## VELOCIDAD EN ENSAYOS DE TENSIÓN

La velocidad de los ensayos a tensión serán aquellas que permitan las lecturas de carga y deformación o las que recomienden los estándares de la ASTM, ASME o alguna otra asociación. Para el tipo de material a ensayar, un ejemplo de velocidades del cabezal móvil serían desde 0.01 a 0.05 plg/min y una máxima velocidad de carga sería 100 kips/plg<sup>2</sup>-min, se sugiere detectar la cedencia en metales según ASTM 8.

## TEXTURA DE GRANO Y TIPOS DE FRACTURA:

Las fracturas se pueden clasificar en cuanto a forma, textura y color de tipos de fracturas más comunes son cono-crater, parcialmente cono y crater, planas e irregulares y las que puedan definirse al momento de la fractura del espécimen los tipos de texturas son sedosa, grano fino, grano grueso, granular fibrosa, estillable, cristalina, vidriosa y mate y las que puedan determinarse al inspeccionar la sección transversal de la pieza (ver figura 3.11).

Figura 3.11

#### **4.- Máquinas para Pruebas Mecánicas, Accesorios e Instrumentos de Medición**

### **MÁQUINAS DE PRUEBAS MECÁNICAS**

Las máquinas empleadas para las diferentes pruebas o ensayos en los materiales, en los diversos productos y pruebas experimentales.

- \* Máquina Universal de Pruebas
- \* Máquina de Dureza Rockwell
- \* Máquina de Dureza Brinell
- \* Máquina de Ductilidad en la Mina Metálica
- \* Máquina de Torsión
- \* Máquina de Fatiga

Cada una de estas máquinas tiene sus correspondientes accesorios o aditamentos para la realización de los ensayos en los materiales, los cuales son recomendados por las agencias que normalizan los ensayos e inspección de los materiales.

Cuando se requiere probar algún producto, por lo común se tiene que hacer o diseñar el aditamento correspondiente. O en su caso lo que sugiera la norma del ensaye.

Enseguida se muestra los catálogos de las máquinas, accesorios y aditamentos.

**SE ANEXAN CATALOGOS RECIENTES DE LAS DIFERENTES.**

**EMPRESAS DISTRIBUIDORAS DE EQUIPO DE PRUEBAS MECÁNICAS**

#### **NOTA:**

Estas máquinas deben de estar en **buen estado, calibradas y certificadas** para su uso, esto dependerá de las recomendaciones que haga el fabricante de las mismas.

## INSTRUMENTOS DE MEDICIÓN

Los instrumentos de medición que se requieren para obtener los datos iniciales y finales sobre el espécimen o muestra son:

- \* **Calibrador para lecturas de dimensiones lineales de tipo:**
  1. Vernier
  2. De Carátula
  3. Digitales
  
- \* **Cinta métrica o flexómetro**
  
- \* **Calibrador de tipo micrometros para la lectura de espesores interiores y exteriores.**
  
- \* **Extensómetro para la medición de desplazamientos lineales de:**
  1. Carátula
  2. Digitales
  
- \* **Indicador de deformación (Puente de Wheatstone)** Considerando los **Straingages** o medidores de deformación eléctricos que se pegan o instrumentan en la pieza a probar para determinar la deformación punto por punto y en cualquier dirección que se desee o se requiera.
  
- \* **Medidor de deformación eléctrico** para colocarlo directamente sobre el material y detectar a través del graficador o en pantalla del monitor de la microcomputadora, si se tiene una máquina programable (automatizada por medio del software) el punto de cedencia del material a probar.
  
- \* **Planímetro:** para la obtención de las áreas de la gráfica de esfuerzo contra deformación para determinar la resiliencia, tenacidad unitarios y pueden ser del tipo:
  1. Mecánico
  2. De Carátula
  3. Digital

### NOTA:

Todos estos instrumentos de medición deben estar en **buen estado, calibrados y certificados** para su uso al igual que si tienen caducidad verificar su reposición ya que influyen en los resultados de las características dimensionales de la pieza o espécimen, al igual que en las propiedades y características mecánicas del material o producto.

Dimensions, mm

Nominal Width	Standard Specimens		Subsize Specimen
	Plate-Type 40 mm	Sheet-Type 12.5 mm	6 mm
1—Gage length (Notes 1 and 2)	200.0 ± 0.2	50.0 ± 0.1	25.0 ± 0.1
2—Width (Notes 3 and 4)	40.0 ± 2.0	12.5 ± 0.2	6.0 ± 0.1
3—Thickness (Note 5)		thickness of material	
4—Radius of fillet, min (Note 6)	25	12.5	6
5—Overall length, min (Notes 2 and 7)	450	200	100
6—Length of reduced section, min	225	57	32
7—Length of grip section, min (Note 8)	75	50	30
8—Width of grip section, approximate (Notes 4 and 9)	50	20	10

NOTE 1—For the 40-mm wide specimen, punch marks for measuring elongation after fracture shall be made on the flat or on the edge of the specimen and within the reduced section. Either a set of nine or more punch marks 25 mm apart, or one or more pairs of punch marks 200 mm apart, may be used.

NOTE 2—When elongation measurements of 40-mm wide specimens are not required, a minimum length of reduced section (A) of 75 mm may be used with all other dimensions similar to the plate-type specimen.

NOTE 3—For the three sizes of specimens, the ends of the reduced section shall not differ in width by more than 0.10, 0.05 or 0.02 mm, respectively. Also, there may be a gradual decrease in width from the ends to the center, but the width at each end shall not be more than 1 % larger than the width at the center.

NOTE 4—For each of the three sizes of specimens, narrower widths (W and C) may be used when necessary. In such cases the width of the reduced section should be as large as the width of the material being tested permits; however, unless stated specifically, the requirements for elongation in a product specification shall not apply when these narrower specimens are used.

NOTE 5—The dimension T is the thickness of the test specimen as provided for in the applicable material specifications. Minimum thickness of 40-mm wide specimen shall be 5 mm. Maximum thickness of 12.5-mm and 6-mm wide specimens shall be 19 mm and 6 mm, respectively.

NOTE 6—For the 40-mm wide specimen, a 13-mm minimum radius at the ends of the reduced section is permitted for steel specimens under 690 MPa in tensile strength when a profile cutter is used to machine the reduced section.

NOTE 7—To aid in obtaining axial loading during testing of 6-mm wide specimens, the overall length should be as large as the material will permit, up to 200 mm.

NOTE 8—It is desirable, if possible, to make the length of the grip section large enough to allow the specimen to extend into the grips a distance equal in two thirds of the length of the grips. If the thickness of 12.5-mm wide specimens is over 10 mm, longer grips and corresponding longer end sections of the specimen may be necessary to prevent failure in the grip section.

NOTE 9—For the three sizes of specimens, the ends of the specimen shall be symmetrical in width with the center line of the reduced section within 2.5, 0.25, and 0.10 mm, respectively. However, for referee testing and when required by product specifications, the ends of the 12.5-mm wide specimen shall be symmetrical within 0.2 mm.

NOTE 10—Specimens with sides parallel throughout their length are permitted, except for referee testing, provided: (a) the above tolerances are used; (b) an adequate number of marks are provided for determination of elongation; and (c) when yield strength is determined, a suitable extensometer is used. If the fracture occurs at a distance of less than 2W from the edge of the gripping device, the tensile properties determined may not be representative of the material. In acceptance testing, if the properties meet the minimum requirements specified, no further testing is required, but if they are less than the minimum requirements, discard the test and retest.

FIG. 1 Rectangular Tension Test Specimens

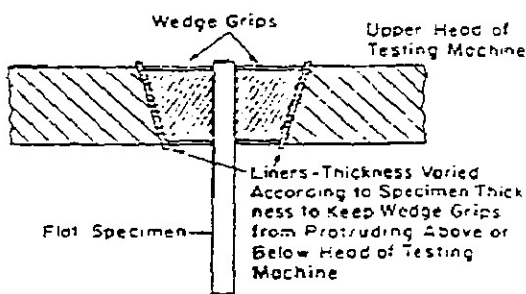

FIG. 2 Wedge Grips with Liners for Flat Specimens

## 8. Report

8.1 Test information on materials not covered by a product specification should be reported in accordance with 8.2 or both 8.2 and 8.3.

8.2 Test information to be reported shall include the following when applicable:

8.2.1 Material and sample identification.

8.2.2 Specimen type (Section 6).

8.2.3 Yield strength and the method used to determine yield strength (see 7.4).

8.2.4 Yield point and the method used to determine yield point (see 7.5).

8.2.5 Tensile strength (see 7.6).

8.2.6 Elongation (report both the original gage length and the percentage increase) (see 7.7).

8.2.7 Reduction of area (see 7.8).

8.3 Test information to be available on request shall include:

8.3.1 Specimen test section dimension(s).

8.3.2 Formula used to calculate cross-sectional area of specimens taken from large-diameter tubular products.

8.3.3 Speed and method used to determine speed of testing (see 7.3).

8.3.4 Method used for rounding of test results (see 7.9).

- 7.10.3 The specimen's properties were changed because of machining practice,
- 7.10.4 The test procedure was incorrect,
- 7.10.5 The fracture was outside the gage length,
- 7.10.6 For elongation determinations, the fracture was outside the middle half of the gage length, or
- 7.10.7 There was a malfunction of the testing equipment.

NOTE 26—The tension specimen is inappropriate for assessing some types of imperfections in a material. Other methods and specimens employing ultrasonics, dye penetrants, radiography, etc., may be considered when flaws such as cracks, flakes, porosity, etc., are revealed during testing and soundness is a condition of acceptance.

	Dimensions, mm				
	Standard Specimen	Small-Size Specimens Proportional To Standard			
	12.5	9	6	4	2.5
G—Gage length	62.5 ± 0.1	45.0 ± 0.1	30.0 ± 0.1	20.0 ± 0.1	12.5 ± 0.1
D—Diameter (Note 1)	12.5 ± 0.2	9.0 ± 0.1	6.0 ± 0.1	4.0 ± 0.1	2.5 ± 0.1
R—Radius of fillet, min	10	8	6	4	2
A—Length of reduced section, min (Note 2)	75	54	36	24	20

NOTE 1—The reduced section may have a gradual taper from the ends toward the center, with the ends not more than 1 % larger in diameter than the center (controlling dimension).

NOTE 2—If desired, the length of the reduced section may be increased to accommodate an extensometer of any convenient gage length. Reference marks for the measurement of elongation should, nevertheless, be spaced at the indicated gage length.

NOTE 3—The gage length and fillets shall be as shown, but the ends may be of any form to fit the holders of the testing machine in such a way that the load may be axial (see Fig. 9). If the ends are to be held in wedge grips it is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two thirds or more of the length of the grips.

NOTE 4—On the round specimens in Figs. 8 and 9, the gage lengths are equal to five times the nominal diameter. In some product specifications other specimens may be provided for, but the 5-to-1 ratio is maintained within dimensional tolerances, the elongation values may not be comparable with those obtained from the standard test specimen.

NOTE 5—The use of specimens smaller than 6 mm in diameter shall be restricted to cases when the material to be tested is of insufficient size to obtain larger specimens or when all parties agree to their use for acceptance testing. Smaller specimens require suitable equipment and greater skill in both machining and testing.

FIG. 8 Standard 12.5-mm Round Tension Test Specimen with Gage Lengths Five Times the Diameters (5D), and Examples of Small-Size Specimens Proportional to the Standard Specimen

	Dimensions, mm				
	Specimen 1	Specimen 2	Specimen 3	Specimen 4	Specimen 5
G—Gage length	62.5 ± 0.1	62.5 ± 0.1	62.5 ± 0.1	62.5 ± 0.1	62.5 ± 0.1
D—Diameter (Note 1)	12.5 ± 0.2	12.5 ± 0.2	12.5 ± 0.2	12.5 ± 0.2	12.5 ± 0.2
R—Radius of fillet, min	10	10	2	10	10
A—Length of reduced section	75, min	75, min	100, approximately	75, min	75, min
L—Overall length, approximate	145	155	140	140	255
B—Length of end section (Note 3)	35, approximately	25, approximately	20, approximately	15, approximately	75, min
C—Diameter of end section	20	20	20	22	20
E—Length of shoulder and fillet section, approximate	....	15	....	20	15
F—Diameter of shoulder	....	15	....	15	15

NOTE 1—The reduced section may have a gradual taper from the ends toward the center with the ends not more than 1 % larger in diameter than the center.

NOTE 2—On Specimens 1 and 2, any standard thread is permissible that provides for proper alignment and aids in assuring that the specimen will break within the reduced section.

NOTE 3—On Specimen 5 it is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two thirds or more of the length of the grips.

FIG. 9 Various Types of Ends for Standard Round Tension Test Specimens

NOTE—The diameter of the plug shall have a slight taper from the line limiting the testing machine jaws to the curved section.

FIG. 11 Metal Plugs for Testing Tubular Specimens, Proper Location of Plugs in Specimen and of Specimen in Heads of Testing Machine

NOTE—The edges of the blank for the specimen shall be cut parallel to each other.

FIG. 12 Location from Which Longitudinal Tension Test Specimens Are to Be Cut from Large-Diameter Tube

Dimensions, mm

Nominal Width	Specimen 1	Specimen 2	Specimen 3
	12.5	40	40
Gage length	50.0 ± 0.1	50.0 ± 0.1	200.0 ± 0.2
Width (Note 1)	12.5 ± 0.2	40.0 ± 2.0	40.0 ± 2.0
Thickness	measured thickness of specimen		
Radius of fillet, min	12.5	25	25
Length of reduced section, min	60	60	230
Length of grip section, min (Note 2)	75	75	75
Width of grip section, approximate (Note 3)	20	50	50

NOTE 1—The ends of the reduced section shall not differ in width by more than 0.1 mm for specimens 1, 2, and 3. There may be a gradual taper in width from the ends to the center, but the width at each end shall be not more than 1% greater than the width at the center.

NOTE 2—It is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two thirds or more of the length of the grips.

NOTE 3—The ends of the specimen shall be symmetrical with the center line of the reduced section within 1.0 mm for specimen 1 and 2.5 mm for specimens 2 and 3.

NOTE 4—Specimens with sides parallel throughout their length are permitted, except for referee testing and where prohibited by product specification, provided: (a) the tolerances are used; (b) an adequate number of marks are provided for determination of elongation; and (c) when yield strength is determined, a suitable extensometer is used. If the fracture occurs at a distance of less than 2W from the edge of the gripping device, the tensile properties determined may not be representative of the material. If the properties meet the minimum requirements specified, no further testing is required, but if they are less than the minimum requirements, discard the specimen and retest.

FIG. 13 Tension Test Specimens for Large-Diameter Tubular Products

FIG. 14 Location of Transverse Tension Test Specimen in Ring Cut from Tubular Products

Dimensions, mm

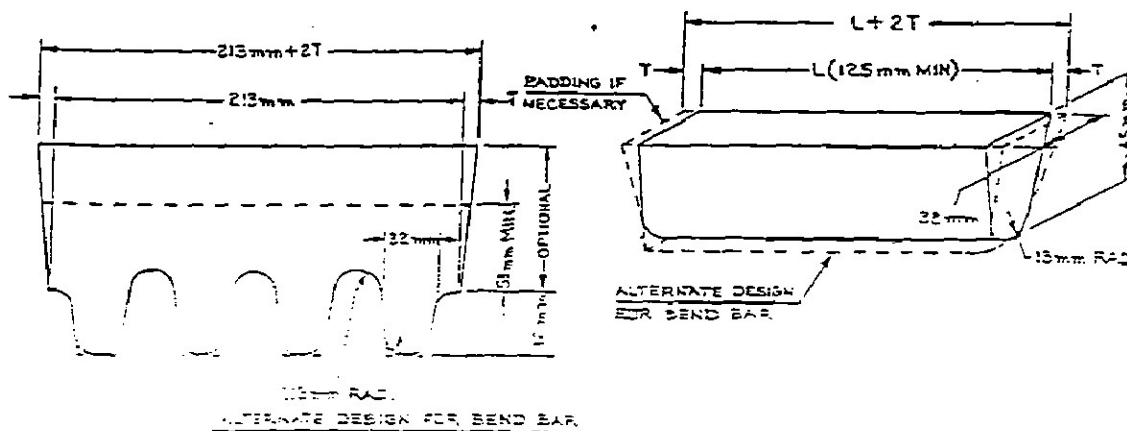

Nominal Diameter	Specimen 1	Specimen 2	Specimen 3
	12.5	20	30
G—Length of parallel	Shall be equal to or greater than diameter D		
D—Diameter	12.5 ± 0.2	20.0 ± 0.4	30.0 ± 0.5
R—Radius of fillet, min	25	25	50
A—Length of reduced section, min	32	38	60
L—Overall length, min	95	100	160
B—Length of end section, approximate	25	25	45
C—Diameter of end section, approximate	20	30	48
E—Length of shoulder, min	6	6	8
F—Diameter of shoulder	16.0 ± 0.4	24.0 ± 0.4	36.5 ± 0.4

NOTE—The reduced section and shoulders (dimensions A, D, E, F, G, and R) shall be as shown, but the ends may be of any form, to fit the holders of the testing machine such a way that the load shall be axial. Commonly the ends are threaded and have the dimensions B and C given above.

**Minimum Hardness**  
 Values are approximate only and this chart is intended primarily as a guide.  
 Specimens thinner than shown in this chart may be tested on the microhardness tester. The thickness of the specimen should be at least 1 1/2 times the diagonal of the indentation when using the 1/16" (1.58 mm) diamond pyramid indenter, and at least 1/2 times the long diagonal when using the Knoop indenter.  
 Values in Chart 55 are consistent with ASTM E18 Tables 4, 5, 11 and 12 for D and G-scale values which appear in *Indentation Hardness Testing* by Vincent E. Lysaght. © 1958 Wilson Instrument Division, Acco.

These corrections are approximate only and represent the averages, to the nearest 1/2 Rockwell number, of numerous actual observations. These values are consistent with ASTM E18 Tables 6, 7, 13 and 14. When testing cylindrical specimens, the accuracy of the test will be seriously affected by alignment of elevating screw, Vee anvil, indenters, surface finish and the straightness of the cylinder.

Dimensions, mm

G—Gage length	$50.0 \pm 0.1$
D—Diameter (see Note)	$6.4 \pm 0.1$
R—Radius of fillet, min	75
A—Length of reduced section, min	60
L—Overall length, min	230
B—Distance between grips, min	115
C—Diameter of end section, approximate	10

NOTE—The reduced section may have a gradual taper from the ends toward the center, with the ends not more than 0.1 mm larger in diameter than the center.

FIG. 18 Standard Tension Test Specimen for Die Castings

Pressing Area =  $645 \text{ mm}^2$

NOTE—Dimensions specified, except G and T, are those of the die.

Dimensions, mm

G—Gage length	$25.40 \pm 0.8$
D—Width at center	$5.72 \pm 0.03$
W—Width at end of reduced section	$5.97 \pm 0.03$
T—Compact to this thickness	3.56 to 6.35
R—Radius of fillet	25.4
A—Half-length of reduced section	15.88
B—Grip length	$80.95 \pm 0.03$
L—Overall length	$89.64 \pm 0.03$
C—Width of grip section	$8.71 \pm 0.03$
F—Half-width of grip section	$4.34 \pm 0.03$
E—End radius	$4.34 \pm 0.03$

FIG. 19 Standard Flat Unmachined Tension Test Specimen for Powder Metallurgy (P/M) Products

Approximate Pressing Area of Unmachined Compact =  $752 \text{ mm}^2$   
Machining Recommendations

1. Rough machine reduced section to 6.35 mm diameter
2. Finish turn 4.75/4.85 mm diameter with radii and taper
3. Polish with 00 emery cloth
4. Lap with crocus cloth

Dimensions, mm

G—Gage length	$25.40 \pm 0.8$
D—Diameter at center of reduced section	$4.75 \pm 0.03$
H—Diameter at ends of gage length	$4.85 \pm 0.03$
R—Radius of fillet	$6.35 \pm 0.13$
A—Length of reduced section	$47.63 \pm 0.13$
L—Overall length (die cavity length)	75, nominal
B—Length of end section	$7.88 \pm 0.13$
C—Compact to this end thickness	$10.03 \pm 0.13$
W—Die cavity width	$10.03 \pm 0.08$
E—Length of shoulder	$6.35 \pm 0.13$
F—Diameter of shoulder	$7.88 \pm 0.03$
J—End fillet radius	$1.27 \pm 0.13$

NOTE 1—The gage length and fillets of the specimen shall be as shown. The ends as shown are designed to provide a practical minimum pressing area. Other end designs are acceptable, and in some cases are required for high-strength sintered materials.

NOTE 2—It is recommended that the test specimen be gripped with a split collet and supported under the shoulders. The radius of the collet support circular edge is to be not less than the end fillet radius of the test specimen.

NOTE 3—Diameters D and H are to be concentric within 0.03 mm total indicator runout (T.I.R.), and free of scratches and tool marks.

FIG. 20 Standard Round Machined Tension Test Specimen for Powder Metallurgy (P/M) Products

## APPENDIX

### (Nonmandatory Information)

#### XI. FACTORS AFFECTING TENSION TEST RESULTS

X1.1 The precision and bias of tension test strength and ductility measurements depend on strict adherence to the stated test procedure and are influenced by instrumental and material factors, specimen preparation, and measurement/testing errors.

X1.2 The consistency of agreement for repeated tests of the same material is dependent on the homogeneity of the material, and the repeatability of specimen preparation, test conditions, and measurements of the tension test parameters.

X1.3 Instrumental factors that can affect test results include: the stiffness, damping capacity, natural frequency, and mass of the tensile test machine, the accuracy of loading and the use of loads within the verified range for the machine, speed of loading, alignment of the test specimen with the applied load, parallelism of the grips, grip pressure, nature of the load control used, appropriateness and calibration of extensometers used, and so forth.

X1.4 Material factors that can affect test results include: representativeness and homogeneity of the test material, sampling scheme, and specimen preparation (surface finish, dimensional accuracy, fillets at the ends of the gage length, taper in the gage length, bent specimens, thread quality, and so forth).

X1.4.1 Some materials are very sensitive to the quality of the surface finish of the test specimen (see Note 11) and must be ground to a fine finish, or polished to obtain correct results.

X1.4.2 Test results for specimens with as-cast, as-rolled, or forged, or other non-machined surface conditions can be affected by the nature of the surface (see Note 12).

X1.4.3 Test specimens taken from appendages to the part or component, such as prolongs or risers, or from separately produced castings (for example, keel blocks) may produce test results that are not representative of the part or component.

X1.4.4 Test specimen size can influence test results. For cylindrical specimens, changing the test specimen size generally has a negligible effect on the yield and tensile strength but may influence the yield point, if one is present, and will influence the elongation and reduction of area values. In general, increasing the specimen size reduces the % elongation and % reduction in area, although some studies have shown no effect, or the opposite effect. For rectangular tensile test specimens, increasing the width or thickness generally increases the % elongation and decreases the % reduction in area.

X1.4.5 Use of a taper in the gage length, up to the allowed % limit, can result in lower elongation values. Reductions as much as 15 % have been reported for a 1 % taper.

X1.4.6 Some materials are highly strain-rate sensitive. Changes in the strain rate can affect the yield strength and elongation values, especially for strain-rate sensitive materials.

In general, the yield strength and elongation will increase as the strain rate increases.

X1.4.7 Brittle materials require careful specimen preparation, high quality surface finishes, large fillets at the ends of the gage length, oversize threaded grip sections, and cannot tolerate punch or scribe marks as gage length indicators.

X1.4.8 Flattening of tubular products to permit testing does alter the material properties, generally nonuniformly, in the flattened region which may affect test results.

X1.5 Measurement errors that can affect test results include: verification of the test force, extensometers, micrometers, dividers, and other measurement devices, alignment and zeroing of chart recording devices, and so forth.

X1.5.1 Measurement of the dimensions of as-cast, as-rolled, as-forged, and other test specimens with non-machined surfaces may be imprecise due to the irregularity of the surface flatness.

X1.5.2 Materials with anisotropic flow characteristics may exhibit non-circular cross sections after fracture and measurement precision may be affected, as a result (see Note 24).

X1.5.3 The corners of rectangular test specimens are subject to constraint during deformation and the originally flat surfaces may be parabolic in shape after testing which will affect the precision of final cross-sectional area measurements (see Note 25).

X1.5.4 If any portion of the fracture occurs outside of the middle of the gage length, or in a punch or scribe mark within the gage length, the elongation and reduction of area values may not be representative of the material. Wire specimens that break at or within the grips may not produce test results representative of the material.

X1.5.5 Use of specimens with shouldered ends ("button-head" tensiles) will produce lower 0.02 % offset yield strength values than threaded specimens.

X1.6 Because standard reference materials with certified tensile property values are not available, it is not possible to rigorously define the bias of tension tests. However, by the use of carefully designed and controlled interlaboratory studies, a reasonable definition of the precision of tension test results can be obtained.

X1.6.1 An interlaboratory test program<sup>8</sup> was conducted where six specimens each, of six different materials were prepared and tested by each of six different laboratories. Tables 2.1 to 2.6 present the precision statistics, as defined in Practice E 691, for: tensile strength, 0.02 % yield strength, 0.2 % yield strength, % elongation in 4D, and % reduction in area. In each table, the first column lists the six materials tested, the second column lists the average of the average results obtained by the laboratories, the third and fifth columns list the repeatability and reproducibility standard deviations, the fourth and sixth columns list the coefficients of variation for these standard deviations, and the seventh

and eighth columns list the 95 % repeatability and reproducibility limits.

X1.6.2 The averages (below columns four and six in each table) of the coefficients of variation permit a relative comparison of the repeatability (within-laboratory precision) and reproducibility (between-laboratory precision) of the test parameters. This shows that the ductility measurements exhibit less repeatability and reproducibility than the strength measurements. The overall ranking from the most repeatable and reproducible is: % elongation in 5D, % reduction in area, 0.02 % offset yield strength, 0.2 % offset yield strength, and tensile strength. Note that the rankings are in the same order for the repeatability and

reproducibility average coefficients of variation and that the reproducibility (between-laboratory precision) is poorer than the repeatability (within-laboratory precision), as would be expected.

X1.6.3 No comments about bias can be made for the interlaboratory study due to the lack of certified test results for these specimens. However, examination of the test results showed that one laboratory consistently exhibited higher than average strength values and lower than average ductility values for most of the specimens. One other laboratory had consistently lower than average tensile strength results for all specimens.

TABLE X1.1 Precision Statistics—Tensile Strength, MPa

Material	$\bar{X}$	$s_r$	$s_r/\bar{X}$ , %	$s_R$	$s_R/\bar{X}$ , %	$r$	$R$

## APPENDIX

### (Nonmandatory Information)

#### X1. FACTORS AFFECTING TENSION TEST RESULTS

X1.1 The precision and bias of tension test strength and ductility measurements depend on strict adherence to the stated test procedure and are influenced by instrumental and material factors, specimen preparation, and measurement/testing errors.

X1.2 The consistency of agreement for repeated tests of the same material is dependent on the homogeneity of the material, and the repeatability of specimen preparation, test conditions, and measurements of the tension test parameters.

X1.3 Instrumental factors that can affect test results include: the stiffness, damping capacity, natural frequency, and mass of the tensile test machine, the accuracy of loading and the use of loads within the verified range for the machine, speed of loading, alignment of the test specimen with the applied load, parallelness of the grips, grip pressure, nature of the load control used, appropriateness and calibration of extensometers used, and so forth.

X1.4 Material factors that can affect test results include: representativeness and homogeneity of the test material, sampling scheme, and specimen preparation (surface finish, dimensional accuracy, fillets at the ends of the gage length, taper in the gage length, bent specimens, thread quality, and so forth).

X1.4.1 Some materials are very sensitive to the quality of the surface finish of the test specimen (see Note 11) and must be ground to a fine finish, or polished to obtain correct results.

X1.4.2 Test results for specimens with as-cast, as-rolled, as-forged, or other non-machined surface conditions can be affected by the nature of the surface (see Note 12).

X1.4.3 Test specimens taken from appendages to the part or component, such as prolongs or risers, or from separately produced castings (for example, keel blocks) may produce test results that are not representative of the part or component.

X1.4.4 Test specimen size can influence test results. For cylindrical specimens, changing the test specimen size generally has a negligible effect on the yield and tensile strength but may influence the yield point, if one is present, and will influence the elongation and reduction of area values. In general, increasing the specimen size reduces the % elongation and % reduction in area, although some studies have shown no effect, or the opposite effect. For rectangular tensile test specimens, increasing the width or thickness generally increases the % elongation and decreases the % reduction in area.

X1.4.5 Use of a taper in the gage length, up to the allowed % limit, can result in lower elongation values. Reductions of as much as 15 % have been reported for a 1 % taper.

X1.4.6 Some materials are highly strain-rate sensitive. Changes in the strain rate can affect the yield strength and elongation values, especially for strain-rate sensitive mate-

rials. In general, the yield strength and elongation will increase as the strain rate increases.

X1.4.7 Brittle materials require careful specimen preparation, high quality surface finishes, large fillets at the ends of the gage length, oversize threaded grip sections, and cannot tolerate punch or scribe marks as gage length indicators.

X1.4.8 Flattening of tubular products to permit testing does alter the material properties, generally nonuniformity, in the flattened region which may affect test results.

X1.5 Measurement errors that can affect test results include: verification of the test force, extensometers, micrometers, dividers, and other measurement devices, alignment and zeroing of chart recording devices, and so forth.

X1.5.1 Measurement of the dimensions of as-cast, as-rolled, as-forged, and other test specimens with non-machined surfaces may be imprecise due to the irregularity of the surface flatness.

X1.5.2 Materials with anisotropic flow characteristics may exhibit non-circular cross sections after fracture and measurement precision may be affected, as a result (see Note 24).

X1.5.3 The corners of rectangular test specimens are subject to constraint during deformation and the originally flat surfaces may be parabolic in shape after testing which will affect the precision of final cross-sectional area measurements (see Note 25).

X1.5.4 If any portion of the fracture occurs outside of the middle of the gage length, or in a punch or scribe mark within the gage length, the elongation and reduction of area values may not be representative of the material. Wire specimens that break at or within the grips may not produce test results representative of the material.

X1.5.5 Use of specimens with shouldered ends ("button-head" tensiles) will produce lower 0.02 % offset yield strength values than threaded specimens.

X1.6 Because standard reference materials with certified tensile property values are not available, it is not possible to rigorously define the bias of tension tests. However, by the use of carefully designed and controlled interlaboratory studies, a reasonable definition of the precision of tension test results can be obtained.

X1.6.1 An interlaboratory test program<sup>8</sup> was conducted where six specimens each, of six different materials were prepared and tested by each of six different laboratories. Tables 2.1 to 2.6 present the precision statistics, as defined in Practice E 691, for: tensile strength, 0.02 % yield strength, 0.2 % yield strength, % elongation in 5D, and % reduction in area. In each table, the first column lists the six material tested, the second column lists the average of the average results obtained by the laboratories, the third and fifth columns list the repeatability and reproducibility standard deviations, the fourth and sixth columns list the coefficient of variation for these standard deviations, and the seventh

and eighth columns list the 95 % repeatability and reproducibility limits.

X1.6.2 The averages (below columns four and six in each table) of the coefficients of variation permit a relative comparison of the repeatability (within-laboratory precision) and reproducibility (between-laboratory precision) of the tension test parameters. This shows that the ductility measurements exhibit less repeatability and reproducibility than the strength measurements. The overall ranking from the least to the most repeatable and reproducible is: % elongation in 4D, % reduction in area, 0.02 % offset yield strength, 0.2 % offset yield strength, and tensile strength. Note that the

rankings are in the same order for the repeatability and reproducibility average coefficients of variation and that the reproducibility (between-laboratory precision) is poorer than the repeatability (within-laboratory precision), as would be expected.

X1.6.3 No comments about bias can be made for the interlaboratory study due to the lack of certified test results for these specimens. However, examination of the test results showed that one laboratory consistently exhibited higher than average strength values and lower than average ductility values for most of the specimens. One other laboratory had consistently lower than average tensile strength results for all specimens.

La máxima resistencia a la tensión y el módulo de elasticidad para cada polímero son:

<i>Polímero</i>	<i>Resistencia a la tensión (psi)</i>	<i>Módulo de elasticidad (ksi)</i>	<i>Estructura</i>
Poliétileno BD	3000	40	Altamente ramificada, amorfa con meros simétricos
Poliétileno AD	5500	180	Amorfa con meros simétricos pero escasa ramificación
Polipropileno	6000	220	Amorfa con pequeños grupos laterales de metilo
Poliestireno	8000	450	Amorfa con grupos laterales de benceno
Cloruro de polivinilo	9000	600	Amorfa con grandes átomos de cloruro como grupos laterales

Se puede concluir que

- (a) La ramificación, que reduce la densidad y la compactación de las cadenas, reduce las propiedades mecánicas del polietileno.
- (b) Añadiendo átomos o grupos diferentes del hidrógeno a la cadena, se incrementan la resistencia y la rigidez. El grupo metilo en el polipropileno proporciona alguna mejoría, el anillo de benceno del estireno proporciona mejores propiedades y el átomo de cloruro en el cloruro de polivinilo proporciona una gran mejora en las propiedades mecánicas.

<i>Polímero</i>	<i>Resistencia a la tensión (psi)</i>	<i>Elongación (%)</i>	<i>Módulo de elasticidad (ksi)</i>
Termoplásticos por adición lineales	3000-12,000	5-800	40-600
Termoplásticos por condensación lineales	8000-17,000	10-300	250-600
Polímeros termoestables	4000-15,000	0-6	500-1,600

Los polímeros por adición lineales tienen la menor resistencia y rigidez pero la mayor ductilidad. Los termoestables tienen la mayor resistencia y rigidez pero son frágiles. La mayoría de los termoplásticos por condensación lineales tiene propiedades intermedias; su estructura molecular es normalmente más compleja que la de los polímeros por adición, pero no están ligados en forma cruzada como los termoestables.

**TABLA 12-5 Grupos funcionales para varios polímeros termoestables**

POLIESTERES (dacrón, mylar, fortrel)	$\text{HOOC}-\text{C}_6\text{H}_4-\text{COOH}$ ACIDO TEREFALICO $\text{HO}-(\text{CH}_2)_N-\text{OH}$ SI $N=2$ ETILENGLICOL	$-\text{C}(=\text{O})-\text{C}_6\text{H}_4-\text{C}(=\text{O})-\text{O}-(\text{CH}_2)_2-\text{O}-$	Polimeros lineales, fibras, cintas magnéticas.
POLIESTERES	 ANHIDRIDO FTALICO $\text{HO}-\text{CH}_2-\text{CH}(\text{OH})-\text{CH}_2-\text{OH}$ GLICERINA		Pinturas, poliesteres de cadena cruzada.
POLIESTERES	$\text{HO}-\text{C}(=\text{O})-\text{CH}=\text{CH}-\text{C}(=\text{O})-\text{OH}$ $\text{HO}-(\text{CH}_2)_N-\text{OH}$ SI $N=2$ ETILENGLICOL	$-\text{C}(=\text{O})-\text{CH}=\text{CH}-\text{C}(=\text{O})-\text{O}-(\text{CH}_2)_N-\text{O}-$	Cadena cruzada con estireno y peróxido: resina-fibra de vidrio.
RESINA FENOL FORMALDEHIDO (BAKOLITA)	 FENOL $\text{CH}_2=\text{O}$ FORMALDEHIDO		Varios resinas, laminas, cartones.
ACETATO DE CELULOSA	 CELULOSA $\text{CH}_3-\text{C}(=\text{O})-\text{OH}$ ACIDO ACETICO		Película fotográfica.

POLIMEROS POR CONDENSACION.

EJEMPLO	MONOMEROS	(UNIDAD MONOMERICA) POLIMERO	USOS
POLIETILENO	$CH_2=CH_2$ ETILENO	$-CH_2-CH_2-$ $[-CH_2-CH_2-]_n$	El más común e importante polímero: bolsas, aislamiento y botellas moldeadas.
POLIPROPILENO	$CH_2=CH$   $CH_3$ PROPILENO	$-CH_2-CH-$   $CH_3$	Fibras para alfombras interiores y exteriores.
POLIESTIRENO	$CH_2=CH$    ESTIRENO	$-CH_2-CH-$   	Moldeo de objetos para uso doméstico e industrial.
POLICLORURO DE VINILO PVC	$CH_2=CH$   Cl CLORURO DE VINILO	$-CH_2-CH-$   Cl	Recubrimiento de pisos acetatos de discos, tubos para agua, envases y botellas transparentes.
POLITETRAFLUORURO DE ETILENO (TEFLON PTFE)	$F$   $C=C$   $F$ TETRAFLURO ETILENO	$-CF_2-CF_2-$	Caras inastillables: resistente a películas químicas.
POLIMETACRILATO DE METILO	$C=C$   $CH_2$   $CH_3$ METIL-META ACRILATO.	$-C(CO_2CH_3)-CH_2-$   $CH_3$	Vidrio irrompible y pinturas latex.
POLIACRILATO NITRICO Goma, acrílico, Gres, etc.	$CH_2=CH$   NO <sub>2</sub> ACRILATO NITRICO	$-CH_2-CH-$   NO <sub>2</sub>	Fibras resistentes en acetato, diformato, etc. acetileno.
POLI-ACETATO DE VINILO	$CH_2=CH$   $C(=O)CH_3$ ACETATO DE VINILO	$-CH_2-CH-$   $C(=O)CH_3$	Adesivos, pinturas latex, capas textiles y gomas de mascar.
HULE NATURAL	$CH_3$   $CH_2=C-CH=CH_2$ CIS-1,4 ISOPRENO	$-CH_2-C(CH_3)=CH-CH_2-$	El polímero con cadenas cruzadas de sulfuro por vulcanización.
POLICLOROPRENO (NEOPRENO)	Cl   $CH_2=C-CH=CH_2$ CLOROPRENO	Cl   $-CH_2-C=CH-CH_2-$	Con cadenas cruzadas de Zn O es resistente a aceites y gasolinas.
ESTIRENO-BUTADIENO (SBR)	$CH=CH$ ESTIRENO    BUTADIENO $CH_2=CH-CH=CH_2$	$-CH_2-CH-CH_2-CH=CH-CH_2-$    BUNA S	Con cadenas cruzadas de peróxido; es el más común hule usado para llantas, contiene 75% butadieno.

\* Wood Handbook (Manual de la Madera), Forest Products Laboratory (Laboratorio de Productos Forestales), U.S. Department of Agriculture (Departamento de Agricultura de los Estados Unidos), 1955.

† Todas las probetas son de madera limpia de grano recto con un contenido de humedad de 12%.

‡ Probeta de 2 X 2 X 50 plg sobre claro de 28 plg.

§ Probeta de 2 X 2 X 9 plg, 6 plg longitud.

¶ Probeta de 2 X 2 X 6 plg, 4 plg bajo carga.

|| 4 plg bajo carga. Resistencia al corte transversal al grano, aproximadamente 5 veces el equivalente de la paralela al grano.

\* Multiplicar por 0.806 para tener Btu·plg/°F·pie<sup>2</sup>·seg. † Multiplicar por 1.8 para tener cm/cm/°C. ‡ Dividir entre 2.54 para tener ohm·pie.

**TABLA 10-8 Designaciones de grado de endurecimiento para aleaciones de cobre**

Hxx—trabajada en frío. (xx indica el grado de trabajo en frío.)

		Reducción porcentual en espesor o diámetro
H01	1/4 dura	10.9
H02	1/2 dura	20.7
H03	3/4 dura	29.4
H04	dura	37.1
H06	extradura	50.1
H08	de resorte duro	60.5
H10	de resorte extra	68.6
H12	de resorte especial	75.1
H14	de superresorte	80.3

Mxx—tal como se manufactura. (xx se refiere al tipo de proceso de fabricación.)

Oxx—recocida. (xx designa el método de recocido.)

OSxxx—recocida para producir un tamaño particular de grano. (xxx se refiere al diámetro del grano en  $10^{-3}$  mm. Por tanto, OS025 señalaría un diámetro de grano de 0.025 mm.)

TB00—tratada por solución.

TF00—endurecida por envejecimiento.

TQxx—templada y revenida. (xx da detalles del tratamiento térmico.)

**TABLA 10-9 Composiciones, propiedades y aplicaciones de algunas aleaciones de níquel y cobalto**

Material	Resistencia a la tensión (psi)	Esfuerzo de fluencia (psi)	Elongación (%)	Aplicaciones
Ni puro (99.9% Ni)				
Recocido	50,000	16,000	45	Resistencia a la corrosión
Trabajado en frío	95,000	90,000	4	
Monel 400 (Ni-31.5% Cu)	78,000	39,000	37	Válvulas, bombas cambiadores de calor
Superalaciones de Ni				
Hastelloy B-2 (Ni-28% Mo)	130,000	60,000	61	Resistencia a la corrosión
MAR-M246 (Ni-10% Co-9% Cr-10% W + Ti, Al, Ta)	140,000	125,000	5	Motores de reacción
DS-Ni (Ni-2% ThO <sub>2</sub> )	71,000	48,000	14	Turbinas de gas
Superalaciones de Fe-Ni				
Incoloy 800 (Ni-46% Fe-21% Cr)	89,000	41,000	37	Cambiadores de calor
Superalaciones de Co				
Havnes 25 (50% Co-20% Cr-15% W-10% Ni)	135,000	65,000	60	Motores de reacción
Estelita 6B (60% Co-30% Cr-4.5% W)	177,000	103,000	4	Resistencia al desgaste por abrasión

Datos de *Metals Handbook*, Vol. 3, 9a. ed., American Society for Metals, 1980.

**TABLA 10-1** Efecto de los mecanismos de endurecimiento en el aluminio y en las aleaciones de aluminio

<i>Material</i>	<i>Resistencia a la tensión (psi)</i>	<i>Esfuerzo de fluencia (psi)</i>	<i>Elongación (%)</i>	<i>Esfuerzo de fluencia (aleación) / Esfuerzo de fluencia (puro)</i>
Aluminio puro recocido (99.999% Al)	6,500	2,500	60	
Aluminio puro comercial (recocido, 99% Al)	13,000	5,000	45	2.0
Endurecido por solución sólida (1.2% Mn)	16,000	6,000	35	2.4
Aluminio puro trabajado en frío un 75%	24,000	22,000	15	8.8
Endurecido por dispersión (5% Mg)	42,000	22,000	35	8.8
Endurecido por envejecimiento (5.6% Zn-2.5% Mg)	83,000	73,000	11	29.2

\* Datos modificados de *Metals Handbook*, Vol. 2, 9a. ed., American Society for Metals, 1979.

**TABLA 10-7** Propiedades de aleaciones típicas de cobre obtenidas por diferentes mecanismos de endurecimiento

<i>Material</i>	<i>Designación de grado de endurecimiento</i>	<i>Resistencia a la tensión (psi)</i>	<i>Esfuerzo de fluencia (psi)</i>	<i>Elongación (%)</i>	<i>Mecanismo de endurecimiento</i>
Cobre puro, recocido		30,300	4,900	60	
Cobre comercialmente puro, recocido para engrosar el tamaño de grano	O5050	32,000	10,000	55	
Cobre comercialmente puro, recocido para afinar el tamaño de grano	O5025	34,000	11,000	55	Tamaño de grano
Cobre comercialmente puro, trabajado en frío	H10	57,000	53,000	4	Endurecimiento por deformación
Cu-35% Zn recocido	O5050	47,000	15,000	62	Solución sólida
Cu-30% Ni tal como se fabrica	M20	55,000	20,000	45	
Cu-10% Sn recocido	O5035	66,000	28,000	68	Solución sólida + Endurecimiento por deformación
Cu-35% Zn trabajado en frío	H10	98,000	63,000	3	
Cu-30% Ni trabajado en frío	H80	84,000	79,000	3	
Cu-2% Be endurecido por envejecimiento	TF00	190,000	175,000	4	Endurecimiento por envejecimiento
Cu-Al templado y revenido	TQ50	110,000	60,000	5	Reacción martensítica
Manganeso bronce fundido	F	71,000	28,000	30	Reacción eutécticoide

Datos de *Metals Handbook*, Vol. 2, 9a. ed., American Society for Metals, 1979.

**TABLA 10-2 Sistema de designación para las aleaciones de aluminio**

Aleaciones para forja		
1xxx	Alum. comercialmente puro (>99% Al)	No envejecido
2xxx	Al-Cu	Endurecible por envejecimiento
3xxx	Al-Mg	No envejecido
4xxx	Al-Si y Al-Mg-Si	Endurecible por envejecimiento si hay magnesio presente
5xxx	Al-Mg	No envejecido
6xxx	Al-Mg-Si	Endurecible por envejecimiento
7xxx	Al-Mg-Zn	Endurecible por envejecimiento
Aleaciones fundidas		
1xx.x	Alum. comercialmente puro	No envejecido
2xx.x	Al-Cu	Endurecible por envejecimiento
3xx.x	Al-Si-Cu ó Al-Mg-Si	Algunas son endurecibles por envejecimiento
4xx.x	Al-Si	No envejecido
5xx.x	Al-Mg	No envejecido
7xx.x	Al-Mg-Zn	Endurecible por envejecimiento
8xx.x	Al-Sn	Endurecible por envejecimiento

**TABLA 10-3 Propiedades de algunas aleaciones de aluminio**

Aleación	Resistencia a la tensión (psi)	Esfuerzo de fluencia (psi)	Elongación (%)	Comentarios	
<b>Aleaciones para forja no tratables térmicamente</b>					
1100-O	>99% Al	13,000	5,000	40	Componentes eléctricos, hojas metálicas finas ("papel"), resistencia a la corrosión.
1100-H18		24,000	22,000	10	
3003-O	1.2% Mn	16,000	6,000	35	Latas para bebidas, aplicaciones arquitectónicas.
3003-H18		29,000	27,000	7	
4043-O	5.2% Si	21,000	10,000	22	
5056-O	5% Mg	42,000	22,000	35	Metal de relleno en soldadura, recipientes, componentes marinos.
5056-H18		60,000	50,000	15	
<b>Aleaciones para forja tratables térmicamente</b>					
2024-O	4.4% Cu	27,000	11,000	20	
2024-T4		68,000	47,000	20	
4032-T6	12% Si-1% Mg	55,000	46,000	9	Transportes, aeronáutica, astronáutica y otras aplicaciones de alta resistencia.
6061-T6	1% Mg-0.6% Si	45,000	40,000	15	
7075-T6	5.6% Zn-2.5% Mg	83,000	73,000	11	
<b>Aleaciones para fundición</b>					
295-T6	4.5% Cu-0.8% Si	36,000	24,000	5	Arena
319-F	6% Si-3.5% Cu	27,000	18,000	2	Arena
356-T6	7% Si-0.3% Mg	34,000	19,000	2.5	Molde permanente
		33,000	24,000	3.5	Arena
		38,000	27,000	5	Molde permanente
380-F	8.5% Si-3.5% Cu	46,000	23,000	3.5	Molde permanente
390-F	17% Si-4.5% Cu-0.6% Mg	41,000	35,000	1	Coquilla
443-F	5.2% Si	19,000	8,000	8	Arena
		23,000	9,000	10	Molde permanente
		33,000	16,000	9	Coquilla
713-T5	7.5% Zn-0.7% Cu-0.35% Mg	30,000	22,000	4	Arena

Datos modificados de *Alcals Handbook*, Vol. 2, 9a. ed., American Society for Metals, 1979.

**TABLA 10-10** Propiedades de algunas aleaciones de titanio

Material	Resistencia a la tensión (psi)	Esfuerzo de fluencia (psi)	Elongación (%)
Titanio comercialmente puro			
99.5% Ti	35,000	25,000	24
99.0% Ti	80,000	70,000	15
Aleaciones Ti alfa			
5% Al-2.5% Sn	125,000	113,000	15

Dimensions

	Standard Specimens		Subsize Specimen
	Plate-Type, 1½-in. Wide	Sheet-Type, ½-in. Wide	¼-in. Wide
	in.	in.	in.
Gage length (Notes 1 and 2)	8.00 ± 0.01	2.000 ± 0.005	1.000 ± 0.003
Width (Notes 3 and 4)	1½ + ⅛, -¼	0.500 ± 0.010	0.250 ± 0.005
Thickness (Note 5)		thickness of material	
Radius of fillet, min (Note 6)	1	½	¼
Over-all length, min (Notes 2 and 7)	18	8	4
Length of reduced section, min	9	2¼	1¼
Length of grip section, min (Note 8)	3	2	1¼
Width of grip section, approximate (Notes 4 and 9)	2	¾	¾

NOTE 1—For the 1½-in. wide specimen, punch marks for measuring elongation after fracture shall be made on the flat or on the edge of the specimen and within the reduced section. Either a set of nine or more punch marks 1 in. apart, or one or more pairs of punch marks 8 in. apart may be used.

NOTE 2—When elongation measurements of 1½-in. wide specimens are not required, a minimum length of reduced section (A) of 2¼ in. may be used with all other dimensions similar to those of the plate-type specimen.

NOTE 3—For the three sizes of specimens, the ends of the reduced section shall not differ in width by more than 0.004, 0.002 or 0.001 in., respectively. Also, there may be a gradual decrease in width from the ends to the center, but the width at each end shall not be more than 0.015, 0.005, or 0.003 in., respectively, larger than the width at the center.

NOTE 4—For each of the three sizes of specimens, narrower widths (W and C) may be used when necessary. In such cases the width of the reduced section should be as large as the width of the material being tested permits; however, unless stated specifically, the requirements for elongation in a product specification shall not apply when these narrower specimens are used.

NOTE 5—The dimension T is the thickness of the test specimen as provided for in the applicable material specifications. Minimum thickness of 1½-in. wide specimens shall be 5/16 in. Maximum thickness of ½-in. and ¼-in. wide specimens shall be 3/4 in. and 1/4 in., respectively.

NOTE 6—For the 1½-in. wide specimen, a ½-in. minimum radius at the ends of the reduced section is permitted for steel specimens under 100 000 psi in tensile strength when a profile cutter is used to machine the reduced section.

NOTE 7—To aid in obtaining axial loading during testing of ½-in. wide specimens, the over-all length should be as large as the material will permit, up to 8.00 in.

NOTE 8—It is desirable, if possible, to make the length of the grip section large enough to allow the specimen to extend into the grips a distance equal to two thirds or more of the length of the grips. If the thickness of ½-in. wide specimens is over 3/4 in., longer grips and correspondingly longer grip sections of the specimen may be necessary to prevent failure in the grip section.

NOTE 9—For the three sizes of specimens, the ends of the specimen shall be symmetrical in width with the center line of the reduced section within 0.10, 0.05 and 0.005 in., respectively. However, for referee testing and when required by product specifications, the ends of the ½-in. wide specimen shall be symmetrical within 0.01 in.

NOTE 10—Specimens with sides parallel throughout their length are permitted, except for referee testing, provided: (a) the above tolerances are used; (b) an adequate number of marks are provided for determination of elongation; and (c) when yield strength is determined, a suitable extensometer is used. If the fracture occurs at a distance of less than 2W from the edge of the gripping device, the tensile properties determined may not be representative of the material. In acceptance testing, if the properties meet the minimum requirements specified, no further testing is required, but if they are less than the minimum requirements, discard the test and retest.

FIG. 1 Rectangular Tension Test Specimens

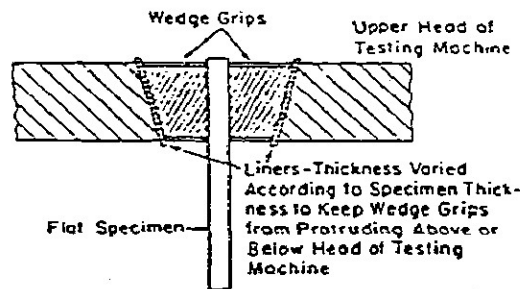

FIG. 2 Wedge Grips with Liners for Flat Specimens

	Dimensions				
	Standard Specimen	Small-Size Specimens Proportional to Standard			
	in.	in.	in.	in.	in.
Nominal Diameter	0.500	0.350	0.250	0.160	0.113
Gage length	2.000 ± 0.005	1.400 ± 0.005	1.000 ± 0.005	0.640 ± 0.005	0.450 ± 0.005
Diameter (Note 1)	0.500 ± 0.010	0.350 ± 0.007	0.250 ± 0.005	0.160 ± 0.003	0.113 ± 0.002
Radius of fillet, min	3/8	1/4	2/16	5/32	3/32
Length of reduced section, min (Note 2)	2 1/4	1 3/4	1 1/4	3/4	3/8

- NOTE 1—The reduced section may have a gradual taper from the ends toward the center, with the ends not more than 1% larger in diameter than the center (controlling dimension).
- NOTE 2—If desired, the length of the reduced section may be increased to accommodate an extensometer of any convenient gage length. Reference marks for the measurement of elongation should, nevertheless, be spaced at the indicated gage length.
- NOTE 3—The gage length and fillets may be as shown, but the ends may be of any form to fit the holders of the testing machine in such a way that the load shall be applied as shown in Fig. 9. If the ends are to be held in wedge grips it is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two thirds or more of the length of the grips.
- NOTE 4—On the round specimens in Figs. 8 and 9, the gage lengths are equal to four times the nominal diameter. In some product specifications other specimens may be provided for, but unless the 4-to-1 ratio is maintained within dimensional tolerances, the elongation values may not be comparable with those obtained from the standard specimen.
- NOTE 5—The use of specimens smaller than 0.250-in. diameter shall be restricted to cases when the material to be tested is of insufficient size to obtain larger specimens or when all parties agree to their use for acceptance testing. Similar specimens require suitable equipment and greater skill in both machining and testing.
- NOTE 6—Five sizes of specimens often used have diameters of approximately 0.505, 0.357, 0.252, 0.160, and 0.113 in., the reason being to permit easy calculations of stress from loads, since the corresponding cross-sectional areas are equal or close to 0.200, 0.100, 0.0500, 0.0200, and 0.0100 in.<sup>2</sup>, respectively. Thus, when the actual diameters agree with these values, the stresses (or strengths) may be computed using the simple multiplying factors 8, 10, 20, 50, and 100, respectively. The main reasons of these five diameters do not result in correspondingly convenient cross-sectional areas and multiplying factors.

FIG. 8 Standard 0.500-in. Round Tension Test Specimen with 2-in. Gage Length and Examples of Small-Size Specimens Proportional to the Standard Specimen

	Dimensions				
	Specimen 1	Specimen 2	Specimen 3	Specimen 4	Specimen 5
	in.	in.	in.	in.	in.
Gage length	2.000 ± 0.005	2.000 ± 0.005	2.000 ± 0.005	2.000 ± 0.005	2.000 ± 0.005
Diameter (NOTE 1)	0.500 ± 0.010	0.500 ± 0.010	0.500 ± 0.010	0.500 ± 0.010	0.500 ± 0.010
Radius of fillet, min	3/8	3/8	1/16	3/8	3/8
Length of reduced section	2 1/4, min	2 1/4, min	4, approximately	2 1/4, min	2 1/4, min
Over-all length, approximate	5	5 1/2	5 1/2	4 3/4	5 1/2
Length of end section (Note 3)	1 3/4, approximately	1, approximately	3/4, approximately	1/2, approximately	3, min
Diameter of end section	3/4	3/4	23/32	7/8	3/4
Length of shoulder and fillet	...	3/8	...	3/8	3/8
Length of end section, approximate	...	...	...	...	...
Diameter of shoulder	...	3/8	...	3/8	3/32

- NOTE 1—The reduced section may have a gradual taper from the ends toward the center with the ends not more than 0.005 in. larger in diameter than the center.
- NOTE 2—On Specimens 1 and 2, any standard thread is permissible that provides for proper alignment and aids in assuring that the specimen will break within the reduced section.
- NOTE 3—On Specimen 5 it is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two thirds or more of the length of the grips.

FIG. 9 Various Types of Ends for Standard Round Tension Test Specimens

Dimensions

	Specimen 1	Specimen 2	Specimen 3	Specimen 4	Specimen 5	Specimen 6	Specimen 7
	in.	in.	in.	in.	in.	in.	in.
Gage length	2.000 ± 0.005	2.000 ± 0.005	8.00 ± 0.01	2.000 ± 0.005	4.000 ± 0.005	2.000 ± 0.005	4.000 ± 0.005
Width (Note 1)	0.500 ± 0.010	1½ + ¼, -¼	1½ + ¼, -¼	0.750 ± 0.031	0.750 ± 0.031	1.000 ± 0.062	1.000 ± 0.062
Thickness	measured thickness of specimen						
Radius of fillet, min	½	1	1	1	1	1	1
Length of reduced section, min	2¼	2¼	9	2¼	4½	¼	4½
Length of grip section, min (Note 2)	3	3	3	3	3	3	3
Width of grip section, approximate (Note 3)	1¼	2	2	1	1	1½	1½

- Note 1—The ends of the reduced section shall differ in width by not more than 0.002 in. for specimen 1, and 4, and not more than 0.005 in. for specimens 2, 3, 5, 6. There may be a gradual taper in width from the ends to the center, but the width at each end shall be not more than 0.005 in. greater than the width at the center for 4-in. gage length specimens, not more than 0.008 in. greater than the width at the center for 8-in. gage length specimens, and not more than 0.015 in. greater than the width at the center for 2-in. gage length specimens.
- Note 2—It is desirable, if possible, to make the length of the grip section great enough to allow the specimen to extend into the grips a distance equal to two thirds the length of the grips.
- Note 3—The ends of the specimen shall be symmetrical with the center line of the reduced section within 0.05 in. for specimens 1, 4, and 5, and 0.10 in. for specimens 2, 3, 6, and 7.
- Note 4—For circular segments, the cross-sectional area may be calculated by multiplying  $W$  and  $T$ . If the ratio of the dimension  $W$  to the diameter of the tubular section is more than about ¼, the error using this method to calculate the cross-sectional area may be appreciable and it may be desirable to use a more exact method for determining the area.
- Note 5—Specimens with  $G/W$  less than 4 should not be used for determination of elongation.
- Note 6—Specimens with sides parallel throughout their length are permitted, except for reference testing, provided that the appropriate gages are used for elongation. If marks are provided for determination of elongation, and (a) when yield strength is determined, a suitable extensometer is used, and (b) the fracture occurs at a distance of less than  $2W$  from the edge of the gripping device, the tensile properties determined may not be representative of the material. If the properties meet the minimum requirements specified, no further testing is required, but if they are less than the minimum requirements, discard the test and retest.

FIG. 13 Tension Test Specimens for Large-Diameter Tubular Products

FIG. 14 Location of Transverse Tension Test Specimen in Ring Cut from Tubular Products

	Dimensions		
	Specimen 1	Specimen 2	Specimen 3
	in.	in.	in.
G—Length of parallel section	Shall be equal to or greater than diameter $D$		
D—Diameter	0.500 ± 0.010	0.750 ± 0.015	1.25 ± 0.02
R—Radius of fillet, min	1	1	2
A—Length of reduced section, min	1¼	1½	2¼
L—Over-all length, min	3¾	4	6¾
B—Length of end section, approximate	1	1	1¾

Although conversion tables dealing with hardness can only be approximate, it is of considerable value to be able to compare different hardness scales. This table is based on the assumption that the metal tested is homogeneous to a depth several times as great as the depth of the indentation.

The indentation hardness values measured on the various scales depend on the work hardening behavior of the material during the test, and this in turn depends on the degree of previous cold working of the material. The B-scale relationships in the table are based largely on annealed metals for the low values and cold worked metals for the
